### ONLINE PAYMENT FRAUD DETECTION USING ML

In the rapidly evolving landscape of digital transactions, the prevalence of online payment fraud has become a significant concern for individuals, businesses, and financial institutions alike. As the volume of online transactions continues to surge, traditional methods of fraud detection are proving inadequate in identifying and preventing sophisticated fraudulent activities. In response to this growing challenge, the integration of machine learning (ML) algorithms has emerged as a powerful tool in bolstering online payment security. It allows for the identification of complex patterns and anomalies in large datasets, enabling organizations to detect and prevent fraudulent transactions in real-time while adapting to evolving tactics employed by fraudsters.

Classification techniques like Decision Tree, Random Forest, and Extra Tree Classifier will be employed. We will use these methods to train and test the data. The optimal model is chosen from this and saved in PKL format.

#### **Technical Architecture:**

Let us look at the Technical Architecture of the project

## **Project flow:**

- Customer is shown the Home page. The customer will browse through Home page and click on the Predict button.
- After clicking the Predict button the customer will be directed to the Predict page where the customer will input the details they have and click on the Predict button.
- Customer will be redirected to the Submit page. The model will analyse the inputs given by the customer and showcase the prediction of the payment.

To accomplish this, we have to complete all the activities listed below

#### Data collection

Collect the dataset or create the dataset.

#### Visualising and analysing data

- Importing the libraries
- Read the Dataset
- Univariate analysis
- Bivariate analysis
- Descriptive analysis

## Data pre-processing

- Checking for null values
- Handling outlier
- Handling categorical(object) data
- Splitting data into train and test

## Model building

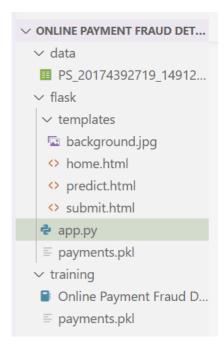

- Import the model building libraries
- Initialising the model
- Training and testing the model
- Evaluating performance of model
- Save the model

### **Application Building**

- Create an HTML file
- Build python code

## **Project Structure:**

Project folder which contains files as shown below:

- The data obtained is in two csv files, one for training and another for testing.
- App.py file is used for routing purposes using scripting.
- Packets.pkl is the saved model.

#### Milestone 1: Data Collection

Link: <a href="https://www.kaggle.com/datasets/rupakroy/online-payments-fraud-detection-dataset">https://www.kaggle.com/datasets/rupakroy/online-payments-fraud-detection-dataset</a>

# Milestone 2: Visualising and analysing data

## **Activity 1: Importing the libraries**

```
import numpy as np
import pandas as pd
import matplotlib.pyplot as plt
import seaborn as sns
from scipy import stats
from sklearn.preprocessing import LabelEncoder
from sklearn.model_selection import train_test_split
from sklearn.ensemble import RandomForestClassifier
from sklearn.metrics import accuracy_score
from sklearn.tree import DecisionTreeClassifier
from sklearn.ensemble import ExtraTreesClassifier
from sklearn.svm import SVC
import xgboost as xgb
from sklearn.metrics import f1_score
from sklearn.metrics import classification_report,confusion_matrix
import warnings
import pickle
```

### **Activity 2: Read the Dataset**

Utilising style use here the ggplot approach Setting "styles"—basically stylesheets that resemble matplotlibrc files—is a fundamental feature of mpltools. The ggplot style, which modifies the style to resemble ggplot, is demonstrated in this dataset.

#### Heatmap:

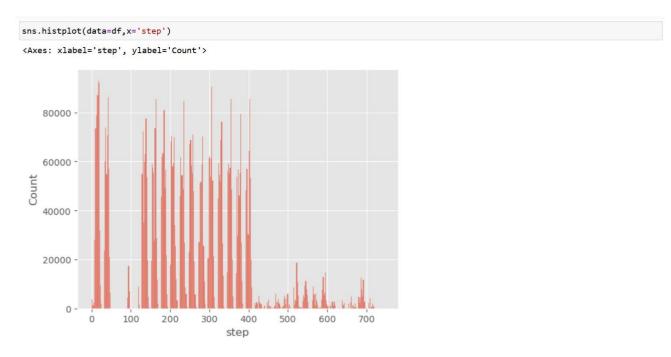

Here, a heatmap is used to understand the relationship between the input attributes and the anticipated goal value.

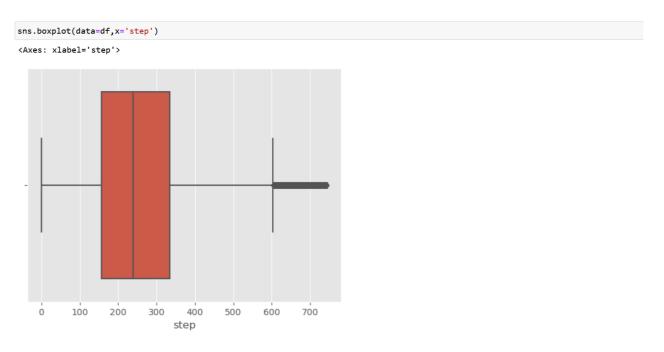

## **Activity 3: Univariate analysis**

In simple words, univariate analysis is understanding the data with a single feature.

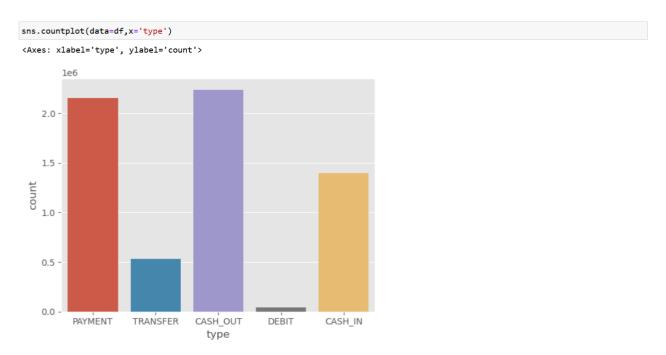

Here we have displayed the graph such as histplot .

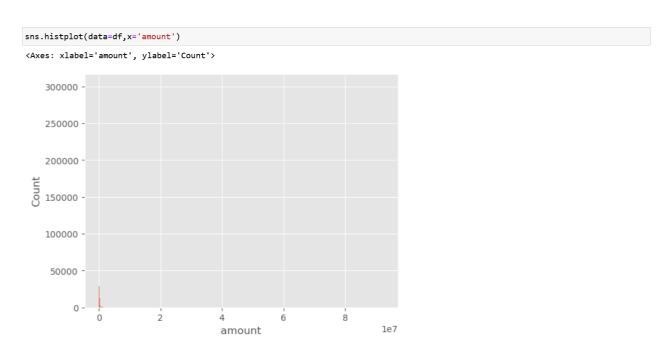

The distribution of one or more variables is represented by a histogram, a traditional visualisation tool, by counting the number of observations that fall within.

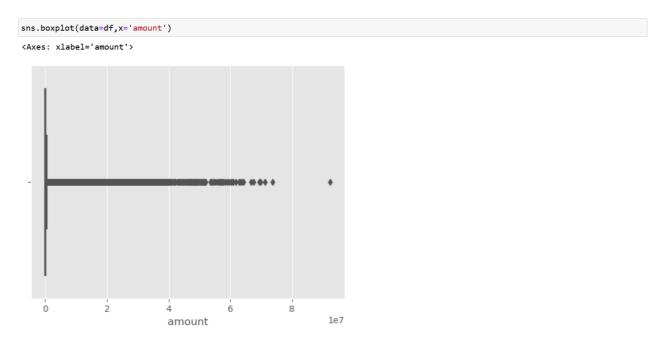

Here, the relationship between the step attribute and the boxplot is visualised.

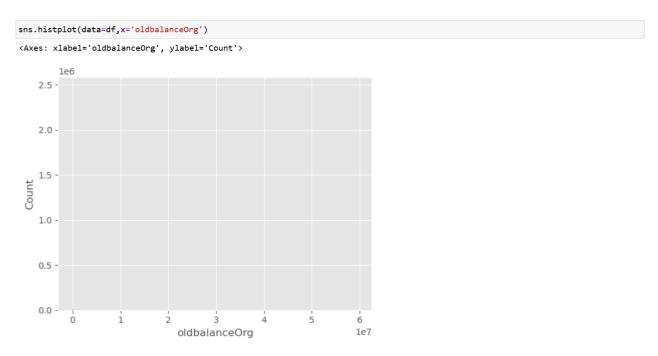

Here, the counts of observations in the type attribute of the dataset will be displayed using a countplot

By creating bins along the data's range and then drawing bars to reflect the number of observations that fall within the amount attribute in the dataset.

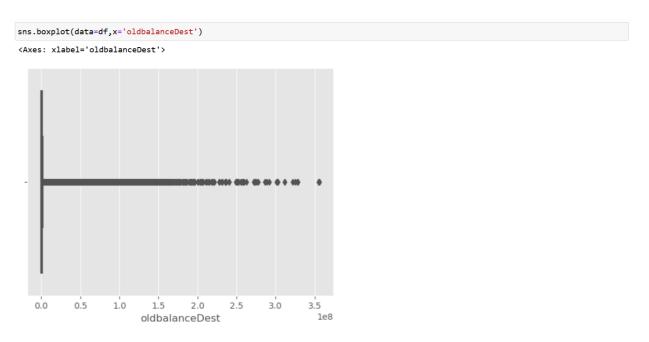

Here, the relationship between the amount attribute and the boxplot is visualised.

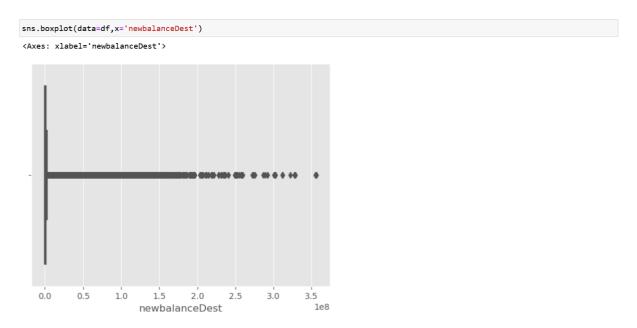

By creating bins along the data's range and then drawing bars to reflect the number of observations that fall within the oldbalanceOrg attribute in the dataset.

```
df['nameDest'].value_counts()
C1286084959
              113
C985934102
               109
C665576141
              105
C2083562754
              102
C248609774
              101
M1470027725
M1330329251
M1784358659
M2081431099
C2080388513
Name: nameDest, Length: 2722362, dtype: int64
```

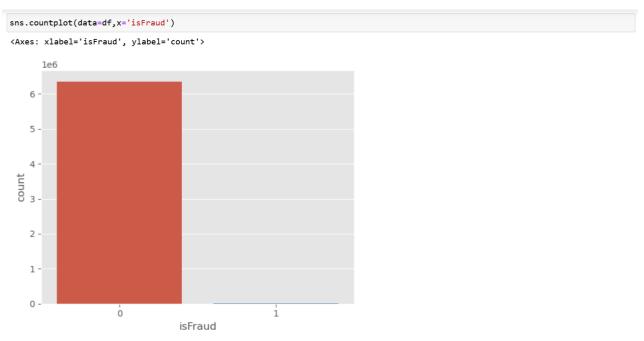

Utilising the value counts() function here to determine how many times the nameDest column appears.

Here, the relationship between the oldbalanceDest attribute and the boxplot is visualised.

Here, the relationship between the newbalanceDest attribute and the boxplot is visualised.

Using the countplot approach here to count the number of instances in the dataset's target is Fraud column.

```
df['isFraud'].value_counts()
0 6354407
       8213
Name: isFraud, dtype: int64
df.loc[df['isFraud'] == 0, 'isFraud'] = 'is not Fraud'
df.loc[df['isFraud'] == 1, 'isFraud'] = 'is Fraud'

850002.52

Converting 0-means: is not fraud and 1-means: is fraud using the loc technique here

## Activity 4: Bivariate analysis

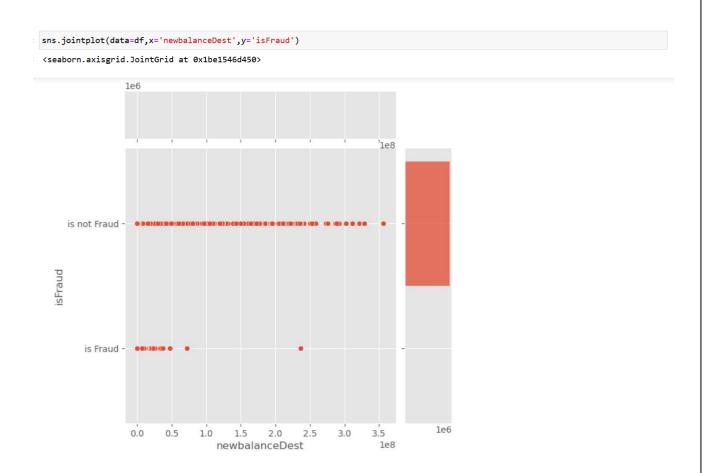

6362616 743 TRANSFER 6311409.28 C1529008245

6362617 743 CASH\_OUT 6311409.28 C1162922333

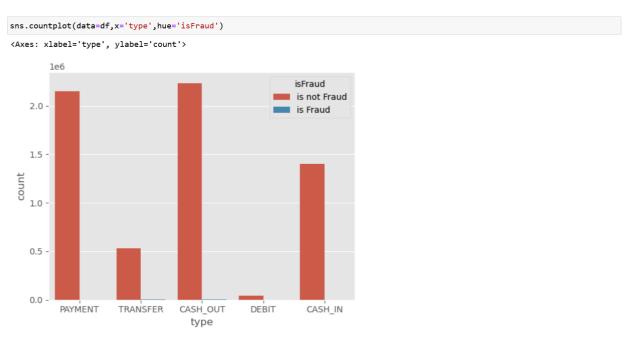

6362618 743 TRANSFER 850002.52 C1685995037

6362619 743 CASH\_OUT 850002.52 C1280323807

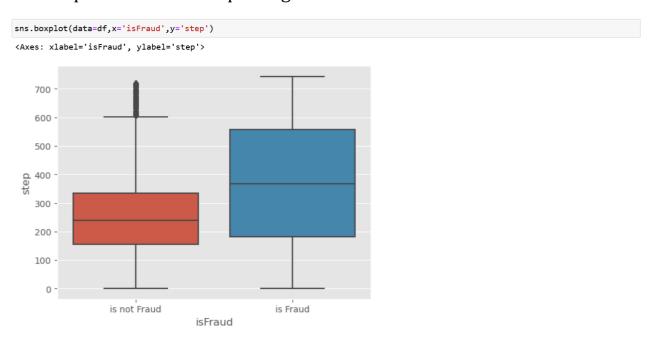

To find the relation between two features we use bivariate analysis. Here we are visualising the relationship between newbalanceDest and isFraud. Jointplot is used here. As a  $1^{st}$  parameter we are passing x value and as a  $2^{nd}$  parameter we are passing hue value.

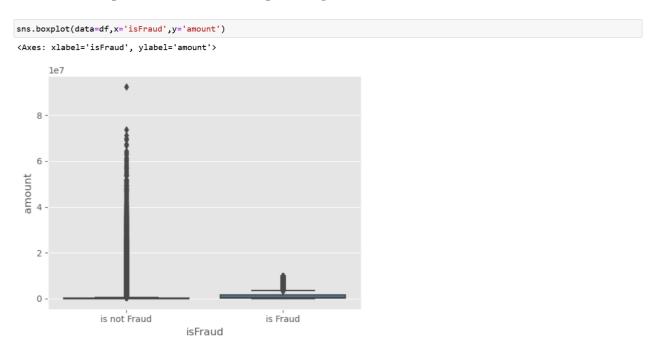

Here we are visualising the relationship between type and is Fraud.countplot is used here. As a  $1^{\rm st}$  parameter we are passing x value and as a  $2^{\rm nd}$  parameter we are passing hue value.

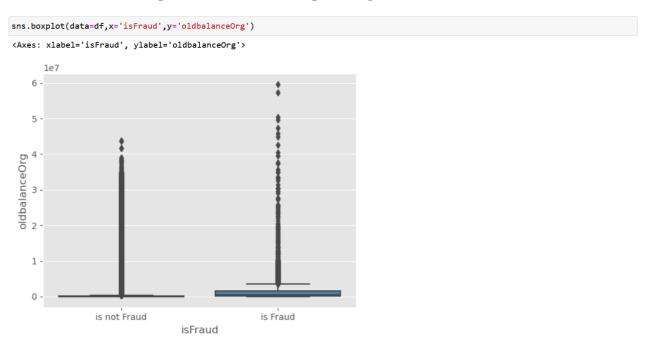

Here we are visualising the relationship between is Fraud and step. boxtplot is used here. As a  $1^{st}$  parameter we are passing x value and as a  $2^{nd}$  parameter we are passing hue value.

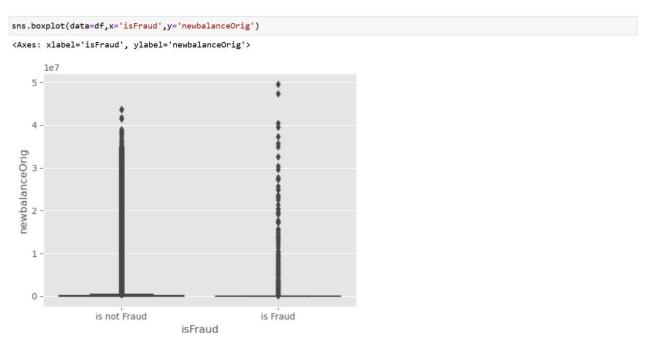

Here we are visualising the relationship between is Fraud and amount. boxtplot is used here. As a  $1^{\rm st}$  parameter we are passing x value and as a  $2^{\rm nd}$  parameter we are passing hue value.

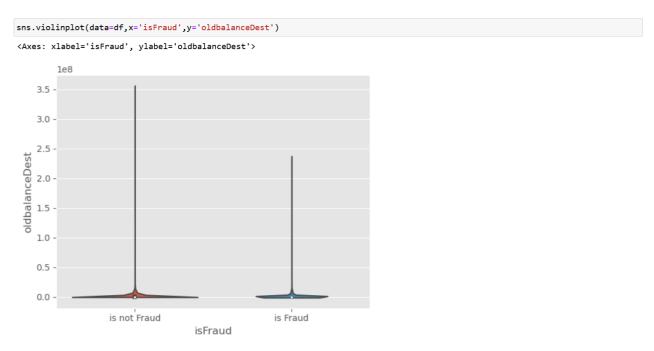

Here we are visualising the relationship between is Fraud and oldbalance Org. Boxtplot is used here. As a  $1^{st}$  parameter we are passing x value and as a  $2^{nd}$  parameter we are passing hue value.

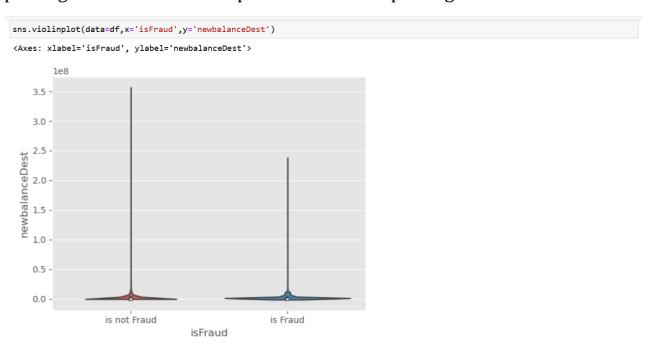

Here we are visualising the relationship between is Fraud and newbalance Orig. Boxtplot is used here. As a  $1^{\rm st}$  parameter we are passing x value and as a  $2^{\rm nd}$  parameter we are passing hue value.

Here we are visualising the relationship between is Fraud and oldbalance Dest. Violinplot is used here. As a  $1^{\rm st}$  parameter we are passing x value and as a  $2^{\rm nd}$  parameter we are passing hue value.

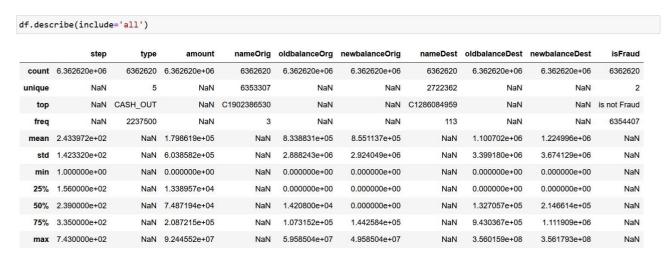

Here we are visualising the relationship between is Fraud and newbalanceDest. Violinplot is used here. As a  $1^{st}$  parameter we are passing x value and as a  $2^{nd}$  parameter we are passing hue value.

#### **Activity 5: Descriptive analysis**

Descriptive analysis is to study the basic features of data with the statistical process. Here pandas has a worthy function called describe. With this describe function we can understand the unique, top and frequent values of categorical features. And we can find mean, std, min, max and percentile values of continuous features.

## Milestone 3: Data Pre-processing

As we have understood how the data is, let's pre-process the collected data. The download data set is not suitable for training the machine learning model as it might have so much randomness so we need to clean the dataset properly in order to fetch good results. This activity includes the following steps.

Handling missing values

Handling Object data label encoding

Splitting dataset into training and test set

Here, I'm using the shape approach to figure out how big my dataset is

```
df.shape
(6362620, 10)
df.drop(['nameOrig', 'nameDest'], axis=1, inplace=True)
df.columns
dtype='object')
df.head
<bound method NDFrame.head of</pre>

## **Activity 1: Checking for null values**

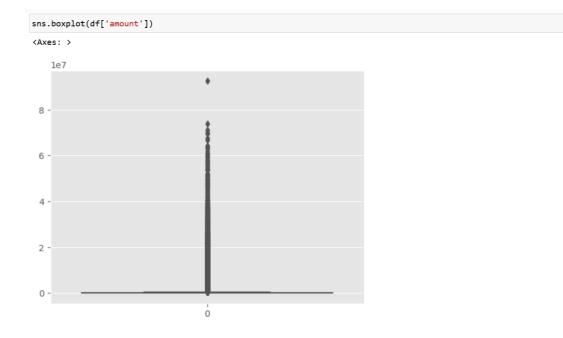

Isnull is used (). sum() to check your database for null values. Using the df.info() function, the data type can be determined.

For checking the null values, data.isnull() function is used. To sum those null values we use the .sum() function to it. From the above image we found that there are no null values present in our dataset. So we can skip handling of missing values step.

```
df.isnull().sum()
step
type
amount
oldbalanceOrg
newbalanceOrig
oldbalanceDest
newbalanceDest
isFraud
dtype: int64
df.info()
<class 'pandas.core.frame.DataFrame'>
RangeIndex: 6362620 entries, 0 to 6362619
Data columns (total 8 columns):
 # Column
 0 step
                            int64
 type object
amount float64
oldbalanceOrg float64
newbalanceDest float64
newbalanceDest float64
newbalanceDest float64
isFraud object
dtypes: float64(5), int64(1), object(2) memory usage: 388.3+ MB
```

# **Activity 2: Handling outliers**

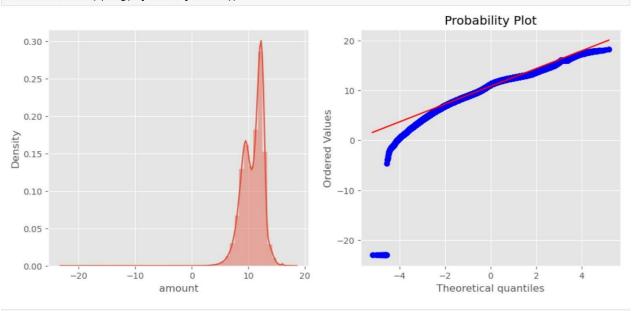

Here, a boxplot is used to identify outliers in the dataset's amount attribute.

#### **Remove the Outliers**

```
from scipy import stats
print(stats.mode(df['amount']))
print(np.mean(df['amount']))
ModeResult(mode=array([10000000.]), count=array([3207]))
179861.90354913071
q1 = np.quantile(df['amount'],0.25)
q3 = np.quantile(df['amount'],0.75)
IQR = q3-q1
upper_bound = q3+(1.5*IQR)
lower_bound = q1-(1.5*IQR)
print('q1 :',q1)
print('q3 :',q3)
print('IQR :',IQR)
print('Upper Bound :', upper_bound)
print('Lower Bound :', lower_bound)
print('Skewed data :',len(df[df['amount']>upper_bound]))
print('Skewed data :',len(df[df['amount']>lower_bound]))
q1 : 13389.57
q3 : 208721.4775
IQR: 195331.9075
Upper Bound : 501719.33875
Lower Bound : -279608.29125
Skewed data : 338078
Skewed data : 6362620
 import numpy as np
 import seaborn as sns
 import matplotlib.pyplot as plt
 from scipy import stats
 def transformationPlot(feature):
      plt.figure(figsize=(12, 5))
      plt.subplot(1, 2, 1)
      sns.distplot(feature)
      plt.subplot(1, 2, 2)
      stats.probplot(feature, plot=plt)
 transformationPlot(np.log(df['amount'] + 1e-10))
```

#### transformationPlot(np.log(df['amount'] + 1e-10))

```
df['amount']=np.log(df['amount'])
```

### Activity 3: Object data labelencoding

```
from sklearn.preprocessing import LabelEncoder
la = LabelEncoder()
df['type'] = la.fit_transform(df['type'])
df['type'].value_counts()
    2237500

# Activity 4: Splitting data into train and test

Now let's split the Dataset into train and test sets

Changes: first split the dataset into x and y and then split the data set. Here x and y variables are created. On x variable, df is passed with dropping the target variable. And my target variable is passed. For

splitting training and testing data we are using the train\_test\_split() function from sklearn. As parameters, we are passing x,y, test\_size, random\_state.

```
from sklearn.model_selection import train_test_split

x_train,x_test,y_train,y_test = train_test_split(x,y,random_state=0,test_size=0.2)

print(x_train.shape)
print(x_test.shape)
print(y_test.shape)
print(y_test.shape)
(5090083, 7)
(1272521, 7)
(1272521,)
(5090083,)
```

## Milestone 4: Model Building

Now our data is cleaned and it's time to build the model. We can train our data on algorithms. For this project we are applying four classification algorithms. The best model is saved based on its performance.

## Activity 1: Random Forest classifier¶

A function named RandomForest is created and train and test data are passed as the parameters. Inside the function, the RandomForestClassifier algorithm is initialised and training data is passed to the model with the .fit() function. Test data is predicted with .predict() function and saved in a new variable. For evaluating the model, a confusion matrix and classification report is done.

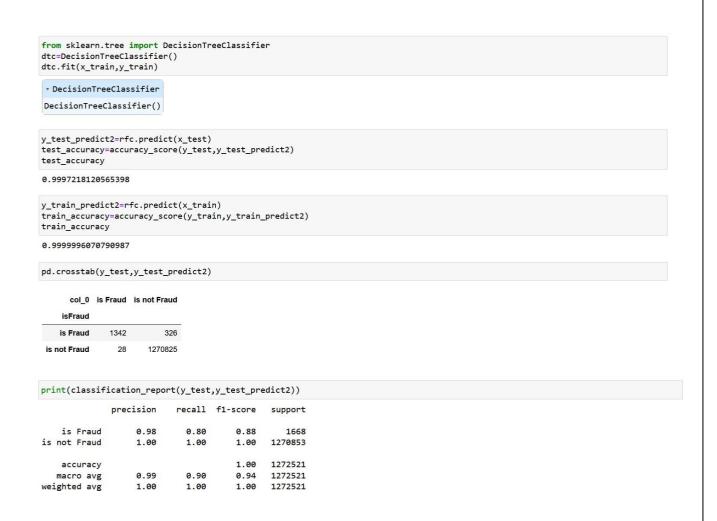

```
from sklearn.ensemble import RandomForestClassifier
from sklearn.metrics import accuracy_score
rfc=RandomForestClassifier()
rfc.fit(x_train,y_train)
RandomForestClassifier
RandomForestClassifier()
y_test_predict1=rfc.predict(x_test)
test_accuracy=accuracy_score(y_test,y_test_predict1)
test_accuracy
0.9997218120565398
y_train_predict1=rfc.predict(x_train)
train_accuracy=accuracy_score(y_train,y_train_predict1)
train_accuracy
0.9999996070790987
pd.crosstab(y_test,y_test_predict1)

        1.00
        1.00
        1272521
```

# **Activity 2: Decision tree Classifier**

A function named Decisiontree is created and train and test data are passed as the parameters. Inside the function, the DecisiontreeClassifier algorithm is initialised and training data is passed to the model with the .fit() function. Test data is predicted with the .predict() function and saved in a new variable. For evaluating the model, a confusion matrix and classification report is done.

## **Activity 3: ExtraTrees Classifier**¶

A function named ExtraTree is created and train and test data are passed as the parameters. Inside the function, ExtraTreeClassifier algorithm is initialised and training data is passed to the model with the .fit() function. Test data is predicted with .predict() function and saved in a new variable. For evaluating the model, a confusion matrix and classification report is done.

```
from sklearn.ensemble import ExtraTreesClassifier
etc=ExtraTreesClassifier()
etc.fit(x_train,y_train)

# Activity 4: Compare the model and Saving the model

For comparing the above four models, the compareModel function is defined.

```
def compareModel():
    print("train accuracy for rfc",accuracy_score(y_train_predict1,y_train))
    print("train accuracy for rfc",accuracy_score(y_test_predict1,y_test))
    print("train accuracy for dtc",accuracy_score(y_train_predict2,y_train))
    print("train accuracy for dtc",accuracy_score(y_train_predict2,y_test))
    print("train accuracy for etc",accuracy_score(y_train_predict3,y_train))
    print("train accuracy for etc",accuracy_score(y_train_predict3,y_train))
    print("train accuracy for etc",accuracy_score(y_test_predict3,y_test))

compareModel()

train accuracy for rfc 0.9999996070790987
train accuracy for dtc 0.9997218120565398
train accuracy for dtc 0.9997218120565398

import pickle
pickle.dump(rfc,open('payments.pk1','wb'))
```

# Milestone 5: Application Building

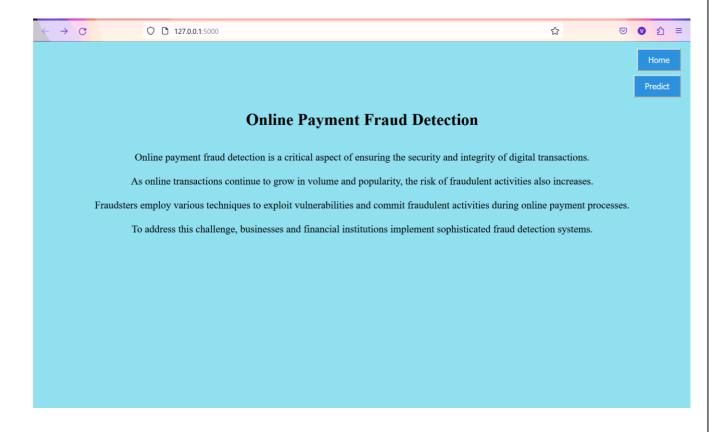

In this section, we will be building a web application that is integrated to the model we built. A UI is provided for the uses where he has to enter the values for predictions. The enter values are given to the saved model and prediction is showcased on the UI.

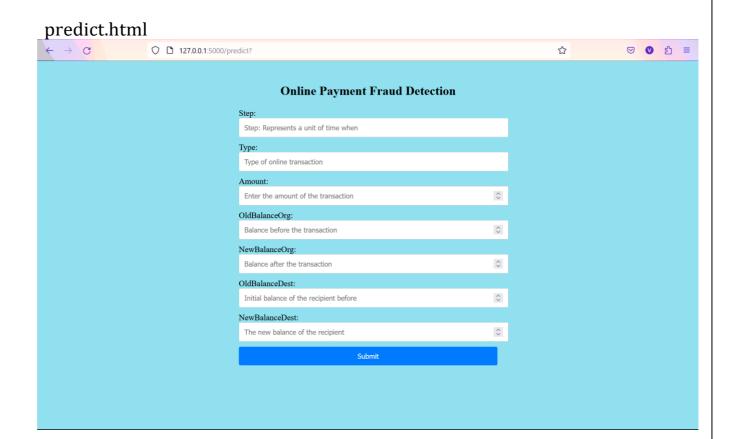

#### **Activity1: Building Html Pages:**

For this project create three HTML files namely

- home.html
- predict.html
- submit.html

Let's see how our home.html page looks like:

### **Activity 2: Build Python code**

Create a new app.py file which will be store in the Flask folder. Import the necessary Libraries.

```
#pip install flask
from flask import Flask, render_template, request
import pickle
import pandas as pd
import numpy as np
from sklearn.preprocessing import StandardScaler
```

This code first loads the saved Random Forest Classifier from the "packets.pkl" file using the "pickle.load()" method. The "rb" parameter indicates that the file should be opened in binary mode to read data from it. After loading the model, the code creates a new Flask web application object named "app" using the Flask constructor. The "name" argument tells Flask to use the current module as the name for the application.

```
# Loading the mlr model
model = pickle.load(open('../training/payments.pkl', 'rb'))
app = Flask(__name__) # your application
```

This code sets up a new route for the Flask web application using the "@app.route()" decorator. The route in this case is the root route "/", which is the default route when the website is accessed. The function "home()" is then associated with this route. When a user accesses the root route of the website, this function is called. The "render\_template()" method is used to render an HTML template named "home.html". The "home.html" is the home page.

```
@app.route('/') # default route
def home():
    return render_template('home.html') # rendering your home page.
```

The route in this case is "/predict". When a user accesses the "/predict" route of the website, this function is "home()" called. The "render\_template()" method is used to render an HTML template named "predict.html".

```
@app.route('/predict')
def predict():
    return render_template('predict.html')
```

This code sets up another route for the Flask web application using the "@app.route()" decorator. The route in this case is "/predict", and the method is set to GET and POST.

#### Main function:

```
@app.route('/submit-form', methods=['POST']) # prediction route
def predict1():
    For rendering results on HTML
    1.1.1
    try:
        # Extracting data from the form
        Step = int(request.form.get('step'))
        Type = int(request.form.get('type'))
        Amount1 = int(request.form.get('amount'))
        Amount2 = int(request.form.get('oldBalanceOrg'))
        Amount3 = int(request.form.get('newBalanceOrg'))
        CardNumber1 = int(request.form.get('oldBalanceDest'))
       CardNumber2 = int(request.form.get('newBalanceDest'))
       # Create a DataFrame from the form data
        input_df = pd.DataFrame({
        'step': [Step],
        'type': [Type],
        'amount': [Amount1],
        'oldbalanceOrg': [Amount2],
        'newbalanceOrig': [Amount3],
        'oldbalanceDest': [CardNumber1],
        'newbalanceDest': [CardNumber2]
    })
        # Make prediction using the pre-trained model
        prediction = model.predict(input_df)
        result_str = str(prediction[0])
```

```
return render_template("submit.html", result="The prediction is " + result_str + "!")
except Exception as e:
    return render_template("submit.html", result="Error: " + str(e))

# running your application
if __name__ == "__main__":
    app.run()
```

# **Activity 3:**

Run the Web Application When you run the "app.py" file this window will open in the console or output terminal. Copy the URL given in the form http://127.0.0.1:5000 and paste it in the browser.

When we paste the URL in a web browser, our home.html page will open and after entering the details in predict.html we will get our submit.html page.
